# Background

Before we proceed, consider this example:

Imagine a stockbroker application with lots of complex capabilities, like

- Downloading the last stock prices
- Checking prices for warnings
- Analyzing historical data for a particular company

These are time-consuming functions. In a single-threaded runtime environment, these actions execute one after another. The next action can happen only when the previous one has finished.

If a historical analysis takes half an hour, and the user selects to perform a download and check afterward, the warning may come too late to buy or sell stock. This is the sort of application that cries out for multithreading. Ideally, the download should happen in the background (that is, in another thread). That way, other processes could happen at the same time so that, for example, a warning could be communicated instantly. All the while, the user is interacting with other parts of the application. The analysis, too, could happen in a separate thread, so the user can work with the rest of the application while the results are being calculated.

This is where a Java thread helps.

# What Is a Java Thread?

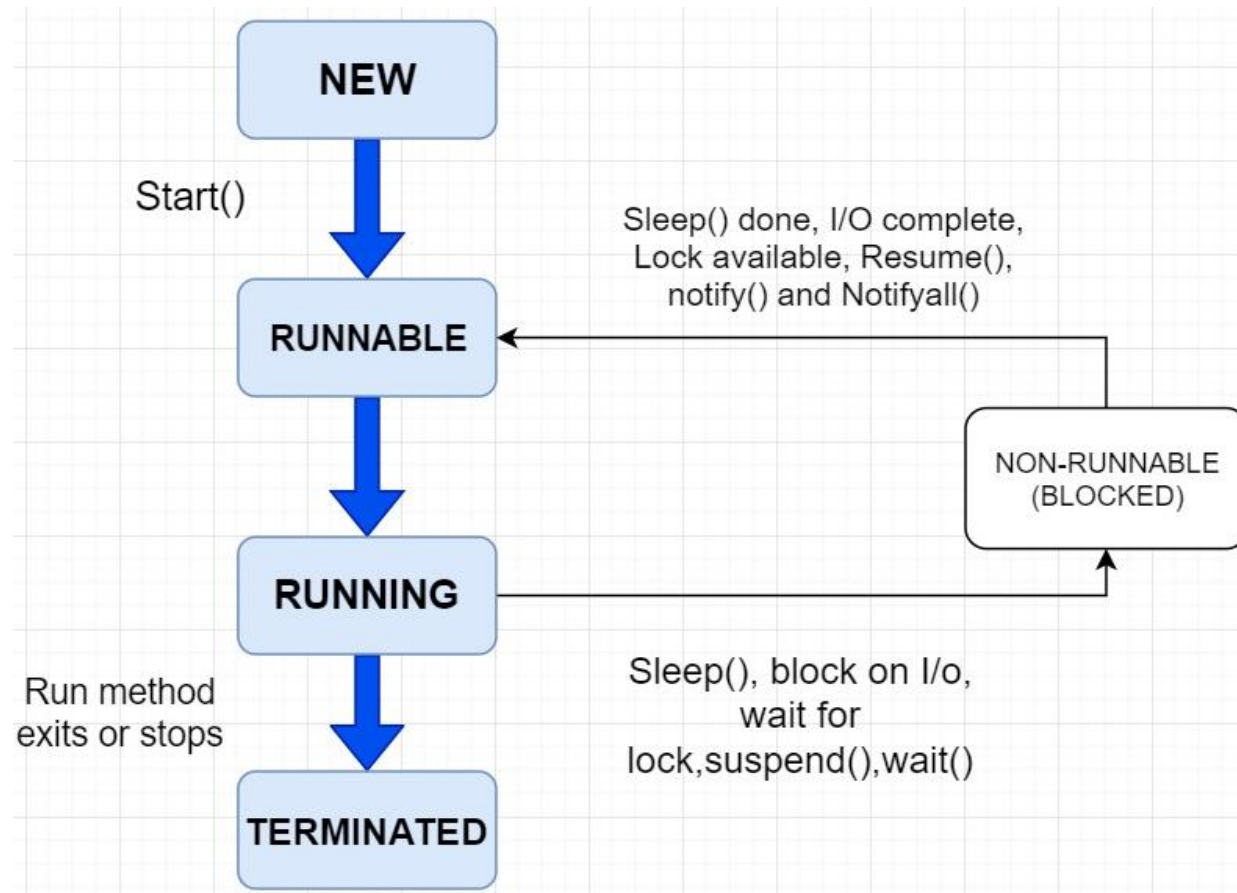

A thread is actually a lightweight process. Unlike many other computer languages, Java provides built-in support for multithreaded programming. A multithreaded program contains two or more parts that can run **concurrently**. Each part of such a program is called a thread and each thread defines a separate path of the execution. Thus, multithreading is a specialized form of multitasking.

## The Java Thread Model

The Java run-time system depends on threads for many things. Threads reduce inefficiency by preventing the waste of CPU cycles.

- Threads exist in several states:
- **New** - When we create an instance of Thread class, a thread is in a new state.
- **Running** - The Java thread is in running state.

- **Suspended** - A running thread can be **suspended**, which temporarily suspends its activity. A suspended thread can then be resumed, allowing it to pick up where it left off.
- **Blocked** - A Java thread can be blocked when waiting for a resource.
- **Terminated** - A thread can be terminated, which halts its execution immediately at any given time. Once a thread is terminated, it cannot be resumed.

# Multithreading in Java: Thread Class and Runnable Interface

Java's multithreading system is built upon the Thread class, its methods, and its companion interface, **Runnable**. To create a new thread, your program will either extend **Thread** or **implement** the **Runnable** interface.

The Thread class defines several methods that help manage threads:

Method	Meaning
getName	Obtain thread's name
getPriority	Obtain thread's priority
isAlive	Determine if a thread is still running
join	Wait for a thread to terminate
run	Entry point for the thread
sleep	Suspend a thread for a period of time
start	Start a thread by calling its run method

# How to Create a Java Thread

Java lets us create a thread one of two ways:

- By **implementing** the **Runnable** interface.
- By **extending** the **Thread**.

## Runnable Interface

- The easiest way to create a thread is to create a class that implements the **Runnable** interface.
- To implement Runnable interface, a class need only implement a single method called `run( )`, which is declared like this:

```
1 public void run( )
```

- Inside `run( )`, we will define the code that constitutes the new thread. Example:

```
1 public class MyClass implements Runnable {
2     public void run(){
3         System.out.println("MyClass running");
4     }
5 }
```

To execute the run() method by a thread, pass an instance of MyClass to a Thread in its constructor (A **constructor in Java** is a block of code similar to a method that's called when an instance of an object is created). Here is how that is done:

```
1 Thread t1 = new Thread(new MyClass ());
2 t1.start();
```

When the thread is started it will call the run() method of the MyClass instance instead of executing its own run() method. The above example would print out the text "**MyClass running**".

# Extending Java Thread

The second way to create a thread is to create a new class that extends Thread, then override the run() method and then to create an instance of that class. The run() method is what is executed by the thread after you call start(). Here is an example of creating a Java Thread subclass:

```
1 public class MyClass extends Thread {  
2     public void run(){  
3         System.out.println("MyClass running");  
4     }  
5 }
```

To create and start the above thread:

```
1 MyClass t1 = new MyClass ();  
2 T1.start();
```

When the run() method executes it will print out the text " **MyClass running** ".
